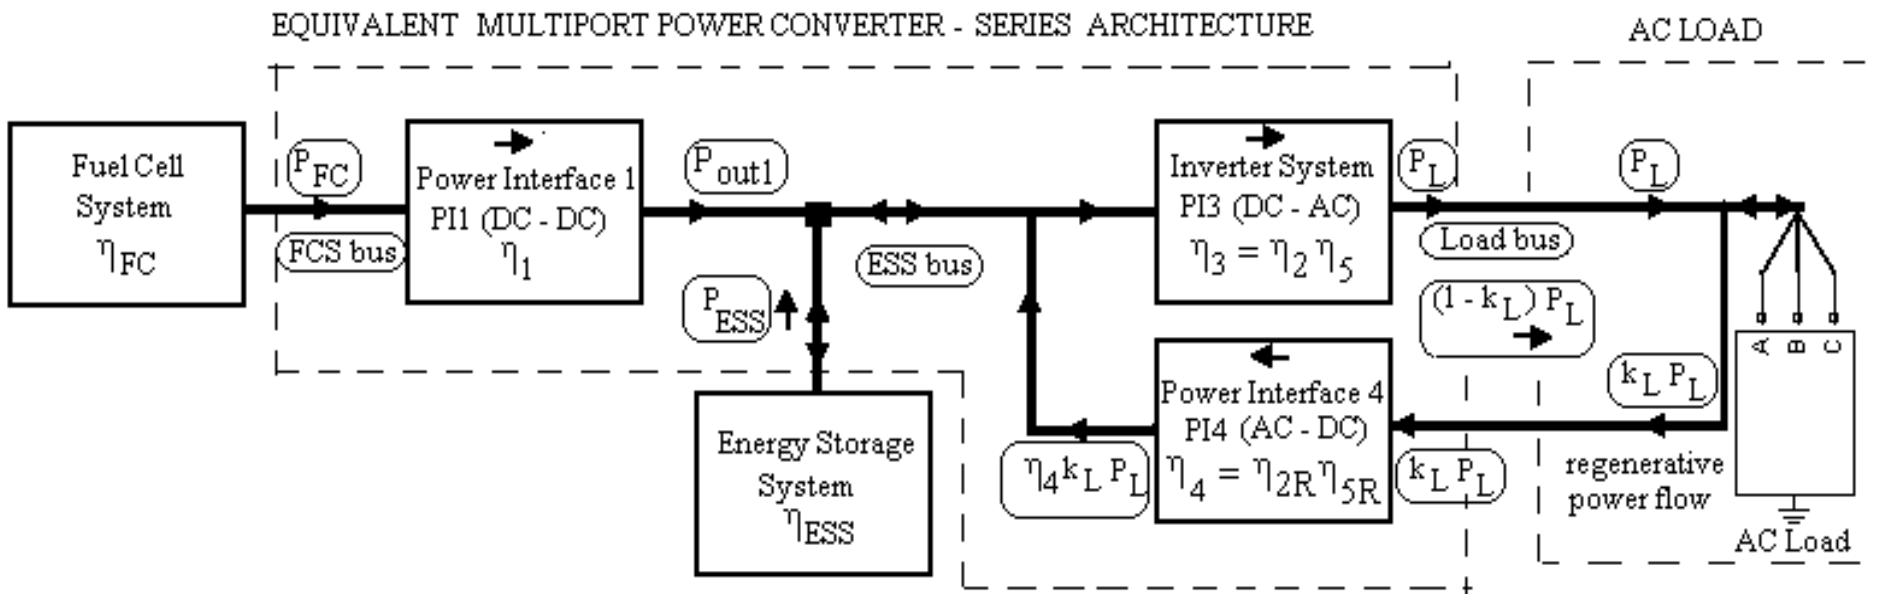

Figure 1.6. Diagram of the MPCs FC HPS architecture

2. Energy efficiency of the MPCp, MPCs, and MPC FC HPS

2.1. Energy efficiency of the MPCp FC HPS

The Energy Storage System (ESS) could operate in following regimes: (1) Charge-Sustaining (CS), (2) Charge-Depleting (CD), and (3) Charge-Increasing (CI).

$P_{ESS(C)}$ and $P_{ESS(D)}$ represent the average power exchanged by the ESS on CI and CD mode.

The FC system powers the load and ESS with $P_{FC(L)}$ and $P_{FC(ESS)}$

The power flow' balance on DC bus in CD mode is:

$$\eta_2 P_{ESS(D)} + \eta_1 P_{FC(L)} = P_L / \eta_5 \quad (1)$$

where the used notations are mentioned above.

The power flow' balance on ESS bus related to CI mode of ESS (which is charged in average with $P_{ESS(C)}$) is:

$$P_{ESS(C)} = \eta_3 P_{FC(ESS)} + \eta_4 k_L P_L = \eta_1 \eta_{2R} P_{FC(ESS)} + \eta_{2R} \eta_{5R} k_L P_L \quad (2)$$

The efficiency analysis will be performed considering as parameters the k_{ESS} and k_{CD} ratios: $k_{ESS(p)} = P_{ESS} / P_L$ and $k_{CD} = P_{ESS(C)} / P_{ESS(D)}$, respectively.

The energy efficiency for MPCp architecture is given by the relation:

$$\eta_p = \eta_{MPCp} = (1 - k_L) P_L / (P_{FC} + P_{ESS}) \quad (3)$$

2. Energy efficiency of the MPCp, MPCs, and MPC FC HPS

2.1. Energy efficiency of the MPCp FC HPS - continued

Relations (6) result by simple mathematical manipulations of (5) using the definitions for $k_{ESS(p)}$ and k_{CD} ratios:

$$P_{ESS(C)} = k_{ESS(p)} k_{CD} P_L / (1 - k_{CD}) \quad (6a)$$

$$P_{ESS(D)} = k_{ESS(p)} P_L / (1 - k_{CD}) \quad (6b)$$

If relations (6) will be used on relations (1) and (2), then relation (4) becomes:

$$P_{FC} = P_L \cdot (1 / \eta_5 - \eta_{5R} k_L - k_{ESS(p)} \eta_{2m}) / \eta_1 \quad (7)$$

where

$$\eta_{2m} = (\eta_2 \eta_{2R} - k_{CD}) / [\eta_{2R} (1 - k_{CD})], \quad k_{CD} \neq 1 \quad (8)$$

It is obvious that:

$$k_{ESS(p)} \begin{matrix} < \\ = \\ > \end{matrix} 0 \Leftrightarrow P_{ESS(D)} \begin{matrix} < \\ = \\ > \end{matrix} P_{ESS(C)} \Leftrightarrow k_{CD} \begin{matrix} > \\ < \end{matrix} 1 \quad (9)$$

where the symbol used for comparison can be $<$, $=$, or $>$.

The case $k_{CD}=1$ ($k_{ESS(p)}=0$) was analyzed in [26]. Considering $k_{CD} \neq 1$, the energy efficiency for MPCp architecture is finally given by relation:

$$\eta_p = (1 - k_L) \eta_1 / [1 / \eta_5 - \eta_{5R} k_L - k_{ESS(p)} (\eta_{2m} - \eta_1)] \quad (10)$$

2. Energy efficiency of the MPCp, MPCs, and MPC FC HPS

2.2. Energy efficiency of the MPCs FC HPS

The ESS bus is powered by the ESS and FC, directly and via PI1, respectively. Using the ratio of ESS power exchanged on ESS bus, $k_{ESS(s)} = P_{ESS}/P_L$, the power flows' balance on ESS bus is:

$$\eta_1 P_{FC} + P_{ESS} + \eta_{2R} \eta_{5R} k_L P_L = P_L / \eta_2 \eta_5 \quad (11)$$

The same relation is obtained if the power flow balance on ESS bus is written in CI and CD mode of ESS, respectively:

$$P_{ESS(C)} = \eta_1 P_{FC(ESS)} + \eta_{2R} \eta_{5R} k_L P_L \quad (12a)$$

$$P_{ESS(D)} + \eta_1 P_{FC(L)} = P_L / \eta_2 \eta_5 \quad (12b)$$

where the notations for the split power flow are the same.

In this case, the energy efficiency for MPCs architecture is given by (13):

$$\eta_s = \eta_{MPCs} = (1 - k_L) P_L / (P_{FC} + P_{ESS}) \quad (13)$$

Using the $k_{ESS(s)}$ ratio, by simple mathematical manipulations of (11), results:

$$\eta_s = (1 - k_L) \eta_1 / [1 / (\eta_2 \eta_5) - \eta_{2R} \eta_{5R} k_L - k_{ESS(s)} (1 - \eta_1)] \quad (14)$$

2. Energy efficiency of the MPCp, MPCs, and MPC FC HPS

2.3. Energy efficiency of MPCp architecture vs. MPCs architecture

If both MPC architectures exchange the same ESS power (positive or negative), i.e. $k_{ESS(p)} = k_{ESS(s)} = k_{ESS}$, it is also important to know which ones operates more efficiently:

$$\eta_p \stackrel{<}{=} \eta_s \quad (15)$$

Relation (15) is equivalent with (16) by using (10) and (14):

$$k_{ESS} \cdot (1 - \eta_{2m}) \stackrel{<}{=} [1 - \eta_2 + k_L \eta_2 (1 - \eta_{2R}) \eta_5 \eta_{5R}] / (\eta_2 \eta_5) \quad (16)$$

Using (8) will result (17):

$$1 - \eta_{2m} = [\eta_{2R} (1 - \eta_2) + k_{CD} (1 - \eta_{2R})] / [\eta_{2R} (1 - k_{CD})], k_{CD} \neq 1 \quad (17)$$

so (16) will become equivalent with (18):

$$\frac{k_{ESS}}{1 - k_{CD}} \stackrel{<}{=} \frac{\eta_{2R}}{\eta_2 \eta_5} \cdot \frac{1 - \eta_2 + k_L \eta_2 (1 - \eta_{2R}) \eta_5 \eta_{5R}}{\eta_{2R} (1 - \eta_2) + k_{CD} (1 - \eta_{2R})}, k_{CD} \neq 1 \quad (18)$$

The following notation is made related to CS mode:

$$\frac{C_{\eta CD}}{1 - k_{CD}} \triangleq \frac{\eta_{2R}}{\eta_2 \eta_5} \cdot \frac{1 - \eta_2 + k_L \eta_2 (1 - \eta_{2R}) \eta_5 \eta_{5R}}{\eta_{2R} (1 - \eta_2) + k_{CD} (1 - \eta_{2R})} > 0, k_{CD} \neq 1 \quad (19)$$

Finally, relation (15) will become equivalent with (20):

$$\frac{k_{ESS}}{1 - k_{CD}} \stackrel{<}{=} \frac{C_{\eta CD}}{1 - k_{CD}}, k_{CD} \neq 1 \quad (20)$$

2. Energy efficiency of the MPCp, MPCs, and MPC FC HPS

2.3. Energy efficiency of MPCp architecture vs. MPCs architecture - continued

If $k_{ESS(p)} = k_{ESS(s)} = k_{ESS}$ then:

$$(|k_{ESS}| < |C_{\eta CD}| \Leftrightarrow \eta_p > \eta_s) \vee (|k_{ESS}| > |C_{\eta CD}| \Leftrightarrow \eta_p < \eta_s) \quad (22)$$

where the \vee symbol is used for the logical OR operator.

Of course, if $k_{ESS(p)} = k_{ESS(s)} = C_{\eta CD}$, then both MPC architectures considered are equivalent in terms of energy efficiency, so $C_{\eta CD}$ is a border value.

If $k_{ESS(p)} \neq k_{ESS(s)}$, then η_p/η_s ratio of energy efficiency coefficients is computed in (23):

$$\frac{\eta_p}{\eta_s} = \frac{1/(\eta_2\eta_5) - \eta_{2R}\eta_{5R}k_L - k_{ESS(s)}(1-\eta_1)}{1/\eta_5 - \eta_{5R}k_L - k_{ESS(p)}(\eta_{2m} - \eta_1)} \quad (23)$$

Simulation results

If is not specifically mentioned, the energy efficiency coefficients of PIs are set in all simulations performed to $\eta_1=0.9$, $\eta_2=0.9$, $\eta_{2R}=0.9$, $\eta_5=0.9$, and $\eta_{5R}=0.9$. The used values for the charge-discharge parameter, k_{CD} , are 1/1.25 and 1.25 for CD and CI operating mode, respectively.

The dependence of energy efficiency for both MPC architectures, considering $k_{ESS(p)} = k_{ESS(s)} = k_{ESS}$, is given by (22) and (23), and is clearly shown in Figure 5 and 6, respectively.

2. Energy efficiency of the MPCp, MPCs, and MPC FC HPS

2.3. Energy efficiency of MPCp vs. MPCs architecture - continued

Figure 5. η_p & η_s for different k_{ESS} and k_L values

Figure 6. $\eta_p/\eta_s(k_{ESS}, k_L)$ surface, using $k_{CD}=1/1.25$ and $k_{CD}=1.25$ in regions where $k_{ESS}>0$ and $k_{ESS}<0$, respectively

Fig. 7. Example of regions where MPCp or MPCs architectures may operate efficiently in CD or CI operating mode

2. Energy efficiency of the MPCp, MPCs, and MPC FC HPS

2.4. Energy efficiency of MPCp vs. MPCs in CS mode

In CS mode the average value of charge exchanged by ESS under a drive (load) cycle is zero, so:

$$k_{ESS} = 0 \Rightarrow P_{ESS0(D)} = P_{ESS0(C)} \quad (25)$$

The energy efficient coefficients given by (10) and (14) become as below:

$$\eta_{p0} = \eta_p \Big|_{k_{ESS(p)}=0} = \frac{(1-k_L)\eta_1}{1/\eta_5 - \eta_{5R}k_L} \quad (10a)$$

$$\eta_{s0} = \eta_s \Big|_{k_{ESS(s)}=0} = \frac{(1-k_L)\eta_1}{1/(\eta_2\eta_5) - \eta_{2R}\eta_{5R}k_L} \quad (14a)$$

where k_L is the regenerative braking factor.

The k_{L-ESS0} coefficient is defined as a measure of load and ESS dynamic:

$$k_{L-ESS0} \stackrel{\Delta}{=} P_{ESS0(D)} / P_L \quad (26)$$

It is also important to know which ones operate more efficiently (for example, see Figure 13):

$$\eta_p \stackrel{<}{>} \eta_s \quad (27)$$

Relation (27) is equivalent with (28) by using (10a) and (14a):

$$k_{L-ESS0} \stackrel{<}{>} \frac{\eta_{2R} [1 - \eta_2 + k_L \eta_2 \eta_{5R} (1 - \eta_{2R})]}{\eta_2 \eta_5 (1 - \eta_2 \eta_{2R})} \stackrel{\Delta}{=} C_{\eta 0} > 0 \quad (28)$$

2. Energy efficiency of the MPCp, MPCs, and MPC FC HPS

2.4. Energy efficiency of MPCp vs. MPCs in CS mode - continued

Figure 13. $\eta_P/\eta_S(k_L, k_{L-ESS0})$ surface for $\eta_1=\eta_2=\eta_{2R}=0.93$ and $\eta_5=\eta_{5R}=1$

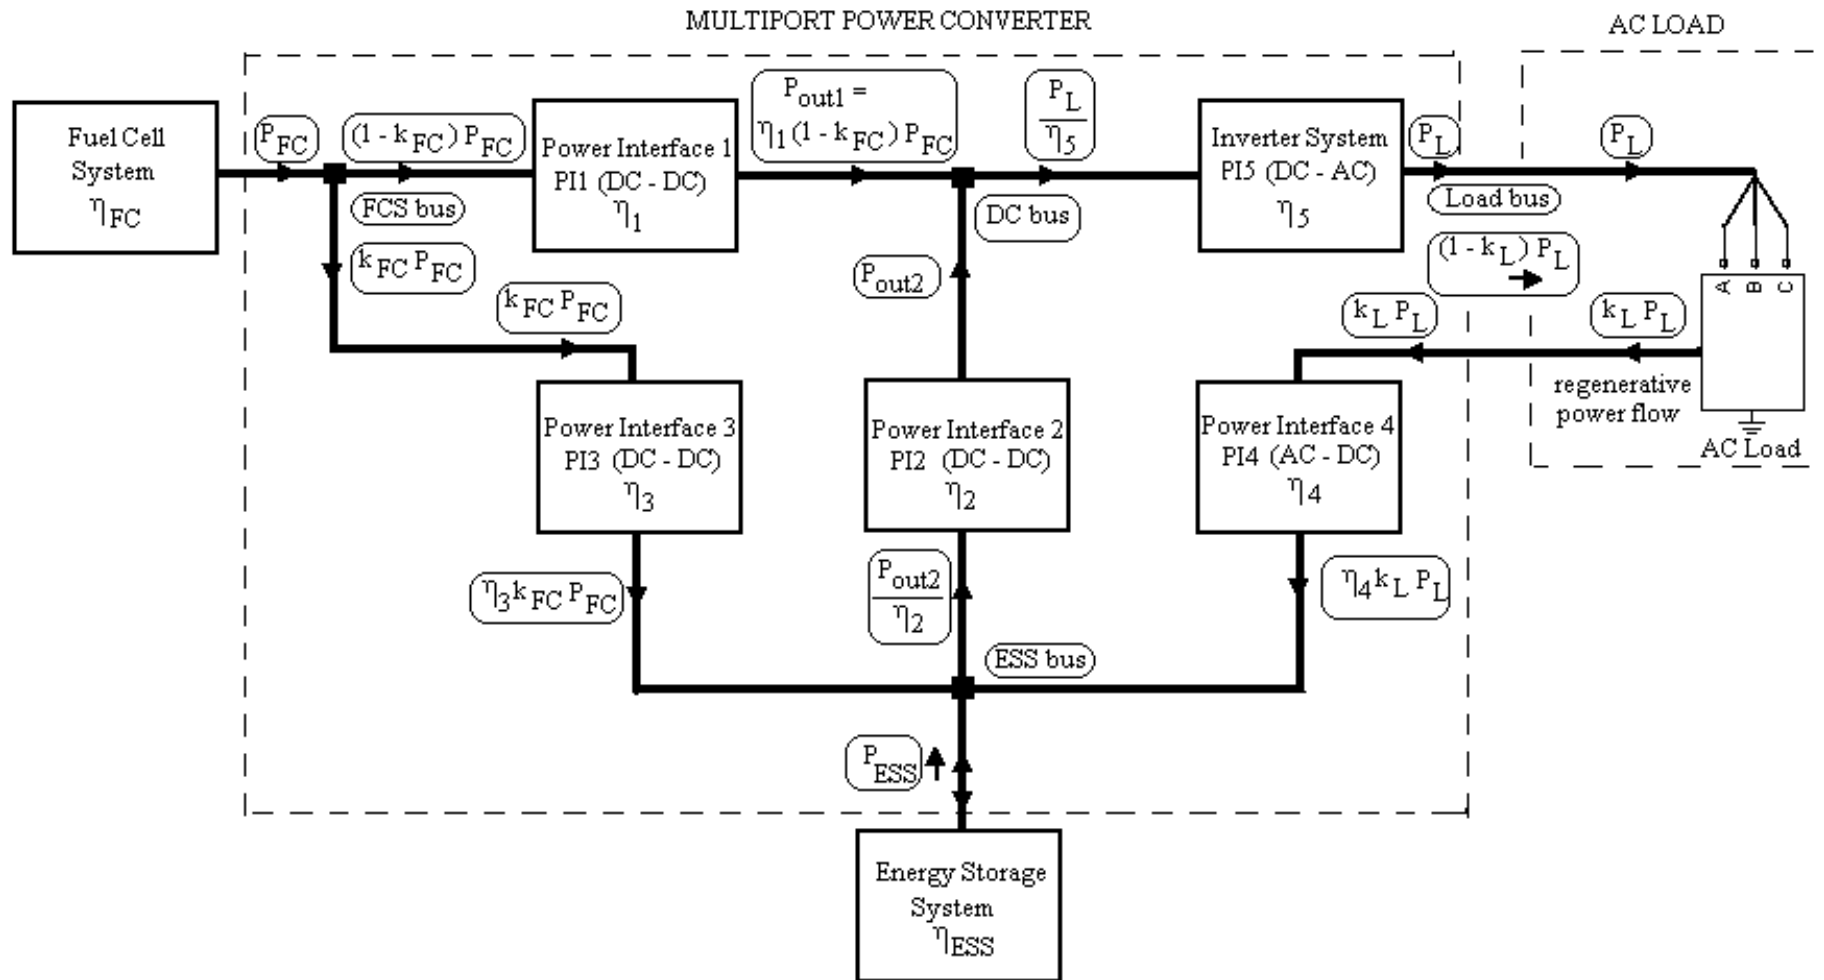

Figure 14. $\eta_S(D_L)$ - line width set to 2, and $\eta_P(D_L)$ - line width set to 1, for $\eta_1=\eta_2=\eta_{2R}=0.93$, $\eta_5=\eta_{5R}=1$, $C_L=9$ and different k_{L-ESS0}

The average (AV) and effective (RMS) value of load power are dependent by the duty cycle, D_L , the ratio of positive and negative amplitudes, $C_L = P_{L(max)} / P_{L(min)}$, and the regenerative braking factor, k_L , as in (29): $P_{L(AV)} = P_L k_L (D_L C_L - 1)$, $P_{L(RMS)} = P_L k_L \sqrt{D_L C_L^2 + 1 - D_L}$

2. Energy efficiency of the MPCp, MPCs, and MPC FC HPS

2.5. Energy efficiency of basic MPC (MPCb)

2. Energy efficiency of the MPCp, MPCs, and MPC FC HPS

2.5. Energy efficiency of basic MPC (MPCb) - continued

The power flows balance on DC bus is:

$$P_{DC}=P_{out1}+P_{out2} \quad (1)$$

The power balance on ESS bus is:

$$P_{ESS}+\eta_3 k_{FC} P_{FC}+\eta_4 k_L P_L=P_{out2}/\eta_2 \quad (2)$$

The energy efficiency for basic MPC architecture is given by relation:

$$\eta_{MPCb}=(1-k_L)P_L/(P_{FC}+P_{ESS}) \quad (3)$$

By simple mathematical manipulations of the first two relations, relation (3) became:

$$\eta_{MPCb}=(1-k_L) \cdot A / B_b \quad (4)$$

where:

$$A=\eta_1+k_{FC}(\eta_2 \eta_3-\eta_1),$$

$$B=1/\eta_5-\eta_2 \eta_4 k_L-k_{ESS} [\eta_2-\eta_1-k_{FC} (\eta_2 \eta_3-\eta_1)], \quad (5)$$

$$B_b = B \Big|_{k_{ESS}=k_{ESSb}} = 1/\eta_5-\eta_2 \eta_4 k_L-k_{ESSb} [\eta_2-\eta_1-k_{FC} (\eta_2 \eta_3-\eta_1)]$$

2. Energy efficiency of the MPCp, MPCs, and MPC FC HPS

2.6. Energy efficiency of MPC without regenerative power flow (MPC1)

In this case, the energy efficiency for MPC1 is given by relation (4) considering $k_L=0$:

$$\eta_{MPC1} = A_1 / B_1 \quad (6)$$

where:

$$A_1 = A|_{k_L=0} = \eta_1 + k_{FC}(\eta_2 \eta_3 - \eta_1),$$

$$B_{\phi 1} = B|_{k_{ESS} = k_{ESS1}} = 1/\eta_5 - \eta_2 \eta_4 k_L - k_{ESS1} [\eta_2 - \eta_1 - k_{FC} (\eta_2 \eta_3 - \eta_1)] \quad (7)$$

$$B_1 = B_{\phi 1}|_{k_L=0} = 1/\eta_5 - k_{ESS1} [\eta_2 - \eta_1 - k_{FC} (\eta_2 \eta_3 - \eta_1)] = B_{\phi 1} + \eta_2 \eta_4 k_L$$

If $k_{ESSb} = k_{ESS1} = k_{ESS(\phi 1)}$, then it is important to know which ones operate more efficiently.

$$\eta_{MPCb} \stackrel{<}{>} \eta_{MPC1} \Leftrightarrow k_{ESS(\phi 1)} \cdot C_{FC} \stackrel{<}{>} C_L \quad (8) \Leftrightarrow (9)$$

$$C_{FC} = \eta_2 - \eta_1 - k_{FC} \cdot (\eta_2 \eta_3 - \eta_1) \quad (10)$$

$$C_L = 1/\eta_5 - \eta_2 \eta_4 > 0$$

So both MPC architectures could have the same efficiency for k_{ESS} given by relation (11):

$$k_{ESS(\phi 1)} = C_L / C_{FC} \quad (11)$$

2. Energy efficiency of the MPCp, MPCs, and MPC FC HPS

2.6. Energy efficiency of MPC1 - continued

If value of k_{ESS} parameter is the same for both MPC architectures (but different to $k_{ESS(b1)}$ value), then energy efficiencies of considered MPC architectures are different, η_{MPCb} and η_{MPC1} , respectively (see Figure 5). From relations (8) and (9) it can be concluded that:

$$|k_{ESS}| < |C_L / C_{FC}| \Rightarrow \eta_{MPCb} < \eta_{MPC1}$$

Figure 5. $\eta_{MPCb}(\eta_1, \eta_2)$ and $\eta_{MPC1}(\eta_1, \eta_2)$ for $k_{FC}=0.1$, $k_L=0.1$, $\eta_3=0.95$, $\eta_4=0.95$, and $\eta_5=0.9$

2. Energy efficiency of the MPCp, MPCs, and MPC FC HPS

2.7. Energy efficiency of MPC without charging power flow from the FC system (MPC2)

In this case, the energy efficiency for MPC is given by relation (4) considering $k_{FC}=0$:

$$\eta_{MPC2} = (1 - k_L) \cdot A_2 / B_2 \quad (14)$$

where:

$$A_2 = A|_{k_{FC}=0} = \eta_1,$$

$$B_{b2} = B|_{k_{ESS}=k_{ESS2}} = 1/\eta_5 - \eta_2 \eta_4 k_L - k_{ESS2} [\eta_2 - \eta_1 - k_{FC} (\eta_2 \eta_3 - \eta_1)] \quad (15)$$

$$B_2 = B_{b2}|_{k_{FC}=0} = 1/\eta_5 - \eta_2 \eta_4 k_L - k_{ESS2} (\eta_2 - \eta_1) = B_{b2} - k_{ESS2} k_{FC} (\eta_2 \eta_3 - \eta_1)$$

If $k_{ESSb} = k_{ESS2} = k_{ESS(b2)}$, then it is important to know which ones operate more efficiently:

$$\eta_{MPCb} \stackrel{<}{>} \eta_{MPC2} \Leftrightarrow C_{kL} \cdot \text{sign}(\eta_2 \cdot \eta_3 - \eta_1) \stackrel{<}{>} k_{ESS(b2)} \cdot \eta_2 \cdot \text{sign}(\eta_2 \cdot \eta_3 - \eta_1) \quad (16) \Leftrightarrow (17)$$

where:

$$C_{kL} = 1 / \eta_5 - \eta_2 \eta_4 k_L > 0 \quad (18)$$

Therefore, if $\eta_2 \cdot \eta_3 \neq \eta_1$, then both MPC architectures have the same efficiency for k_{ESS} value given by relation:

$$k_{ESS(b2)} = C_{kL} / \eta_2 > 0 \quad (19)$$

2. Energy efficiency of the MPCp, MPCs, and MPC FC HPS

2.7. Energy efficiency of MPC2 - continued

If different values for k_{ESS} parameter are used in the operation of MPCb and MPC2 architectures (noted with k_{ESSb} and k_{ESS2} , respectively), then MPC architectures could have the same efficiency:

$$\eta_{MPCb} = \eta_{MPC2} \Rightarrow k_{ESSb} = -C_{KL} / \eta_1 + [C_{FC} / k_{FC} - (\eta_2 - \eta_1) / \eta_1] \cdot k_{ESS2}$$

The relation above for $k_{FC}=0.1$, $k_L=0.1$, $\eta_3=0.95$, $\eta_4=0.95$, $\eta_5=0.9$ and different k_{ESS2} values (negative and positive) is shown in Figure 8.

Figure 8. $k_{ESSb}(\eta_1, \eta_2)$ for $k_{FC}=0.1$, $k_L=0.1$, $\eta_3=0.95$, $\eta_4=0.95$, $\eta_5=0.9$ and different k_{ESS2} values

2. Energy efficiency of the MPCp, MPCs, and MPC FC HPS

2.8. Energy efficiency of MPC1, MPC2, and MPCb

$$\eta_{MPC1} = \eta_{MPC2} \Rightarrow \begin{cases} k_{ESS1} \{ [k_{FC} (\eta_2 \eta_3 - \eta_1) + \eta_1 k_L] \cdot [1 / \eta_5 - \eta_2 \eta_4 k_L + \eta_1 - \eta_2] + \eta_1 - \eta_2 \} - \\ - k_{ESS2} [\eta_1 k_{FC} (1 - k_L) + \eta_1 - \eta_2] = \eta_1 \eta_2 \eta_4 k_L (1 - k_L) \end{cases}$$

$$\{ [\eta_2 \eta_3 > \eta_1] \vee [\eta_2 > \eta_1 > \eta_2 \eta_3] \} \wedge \{ k_{ESS} > C_L / C_{FC} > 0 \} \Leftrightarrow \eta_{MPCb} > \eta_{MPC1}, \forall k_{FC} \in [0, 1]$$

$$\{ \eta_2 \leq \eta_1 \} \wedge \{ 0 \leq (\eta_1 - \eta_2) / (\eta_1 - \eta_2 \eta_3) < k_{FC} \leq 1 \} \wedge \{ k_{ESS} > C_L / C_{FC} > 0 \} \Leftrightarrow \eta_{MPCb} > \eta_{MPC1}$$

$$\{ \eta_2 \leq \eta_1 \} \wedge \{ 0 \leq k_{FC} \leq (\eta_1 - \eta_2) / (\eta_1 - \eta_2 \eta_3) \leq 1 \} \wedge \{ k_{ESS} < C_L / C_{FC} < 0 \} \Leftrightarrow \eta_{MPCb} > \eta_{MPC1}$$

$$\{ \eta_2 \eta_3 > \eta_1 \} \wedge \{ 0 \leq k_L < 1 / \eta_2 \eta_4 \eta_5 \} \wedge \{ k_{ESS} > C_{kL} / \eta_2 > 0 \} \Leftrightarrow \eta_{MPCb} > \eta_{MPC2}$$

$$\{ \eta_2 \eta_3 < \eta_1 \} \wedge \{ 0 \leq k_L < 1 / \eta_2 \eta_4 \eta_5 \} \wedge \{ k_{ESS} < C_{kL} / \eta_2 \} \Leftrightarrow \eta_{MPCb} > \eta_{MPC2}$$

So, basic MPC architecture may operate efficiently for all k_L values of regenerative braking factor in range, if proper EMU control of k_{FC} ratio is performed in all ESS operating modes.

4. Preliminary experimental results.

Mecro System
Mr. Radu PETRE
100 P, Timisoara Blvd
Bucharest-6, RO-061334
Roumanien

Dear Sir,

It is our pleasure to write this letter in support of the research activities developed by S.C. Mecro System S.R.L. in implementing PEM fuel cells in mass-produced electric vehicles.

We are proud that our e-WOLF vehicle, purchased by S.C. Mecro System S.R.L. in 2012, is a key element of the infrastructure involved in the research and development activities focused on assessing the potential of hydrogen technologies as part of the future of road transport.

As a company that integrates leading edge technology in the field of electric vehicles, we would like to express our interest in the outcomes of the R&D activity that could bring significant progress to the transport sector.

We would like to state our availability at any given time for a meeting concerning the technical aspects of innovative projects involving our products.

To conclude with, we completely support S.C. Mecro System S.R.L.'s efforts of developing new technologies that will allow more efficient and environmentally friendly transport solutions.

Sincerely,

Managing Director
Dipl. Kfm. Frank Maiworm

5. Conclusions of Part 2.

Hybrid architectures for the interconnection of Fuel Cell (FC) system and Energy Storage Devices (ESD) are briefly shown here.

Energy management strategies of the Hybrid Power Source (HPS) are introduced here.

The components of the FC Hybrid Power Source (FC HPS) under test are shown.

Energy Management Strategy (EMS) based on Proportional-Integral control was analyzed the FC HPS.

Some preliminary experimental results are presented.

The advantages of this new FC HPS topologies are:

- increasing the life of FC stack by running efficiently at constant power inside of one zone;**
- protecting the ultracapacitors' stack (UCs) to be discharged below 20% SOC;**
- a reduction in hydrogen consumption by 11.8% compared to a FC HPS without UCs.**

These results will be the reference for other EMSs proposed.

Table 2.2. FCV parameters

Parameter	Value
Vehicle weight	1540 kg
Efficiency of the transmission (electric motor \ inverter)	90%
Rolling radius of the wheel	0.25 m
Vehicle frontal area (A)	2.05 m ²
The air drag coefficient (C_w)	0.3
The coefficient of rolling resistance (C_r)	0.01
Air density	1.23 kg/m ³

1. Powertrain architecture of the FC vehicle (FCV)

1.2. Modeling of the FCV

The traction force (F_t) is

$$F_t(t) = m_v(t) \frac{d}{dx}(v(t)) + F_a(t) + F_r(t) + F_g(t)$$

where, F_a is the air resistance force, F_r is the rolling resistance, F_g is the gravity force:

$$F_a = 0.5 * \rho * c_W * A * v^2$$

$$F_r = C_r * m_v(t) * g \cos(\alpha)$$

$$F_g = m_v(t) * g * \sin(\alpha)$$

3. Energy management strategies (EMS) for FC HPS

2.6 Objectives for the EMS unit

- Assuring the load demand
- Operating the FC stack at high efficiency
- Minimizing the fuel consumption
- Protecting the FC stack to fuel starvation
- Protecting the batteries' stack to deep discharge by monitoring the State-Of-Charge (SOC)

The EMS can be mainly classified into rule-based energy management strategy and optimization-based energy management strategy.

Several energy management control strategies have been already proposed for FC vehicle, such as heuristic strategies, equivalent consumption minimization strategy (ECMS) and strategies based on optimal control theory.

Not all objectives mentioned above can be optimized simultaneously.

Below, the following two EMS types will be evaluated:

- Strategies using the control diagram based on the operating states designed;
- PI controllers-based strategies;

3. Energy management strategies (EMS) for FC HPS

2.6 EMS based on PI regulator

IF $SoC \in [65, 85]$ & $P_{load} \geq P_{fc_{max}}$	$State = 6$	$P_{fc}^* = P_{fc_{max}}$
IF $SoC < 60$ & $P_{load} < P_{fc_{max}}$	$State = 7$	$P_{fc}^* = P_{fc_{load}} + P_{charge}$
IF $SoC < 60$ & $P_{load} \geq P_{fc_{max}}$	$State = 8$	$P_{fc}^* = P_{fc_{max}}$

3. Energy management strategies for FC HPS

2.6 Matlab-Simulink diagram of the EMS based states' diagram

4. Results

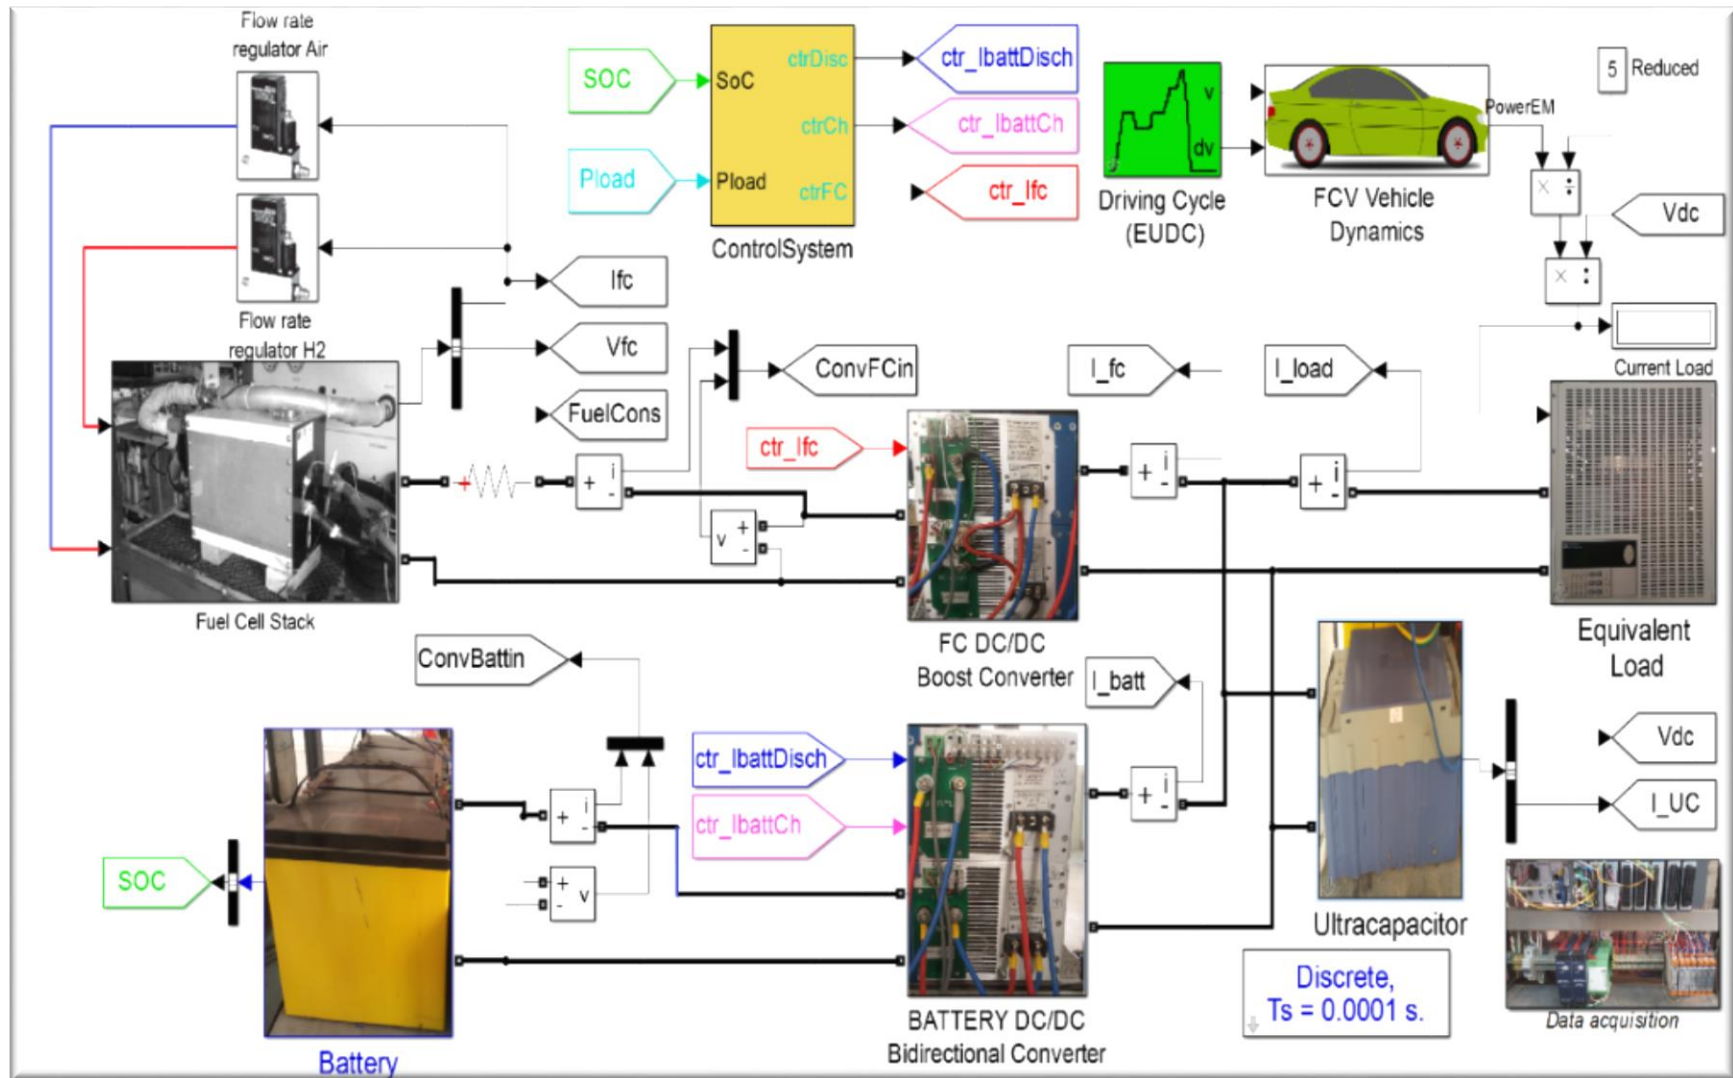

Figure 5.1. Matlab-Simulink diagram of the FCV

4. Results

The EUDC driving cycle is divided into 14 areas, which are shown in next Figures.

Zone 1: At first the vehicle is stopped for a period of 20 seconds; in this zone 1 the fuel cell operates at minimum output of 3910W; this power is used to charge the battery system.

Zone 2: the vehicle accelerates slightly to 70 km / h in 41 seconds (simulated vehicle gearbox is automatic). Depending on EMS implemented, the power flows are different.

Zone 3: the vehicle is moving at a speed of 70 km / h for 50 seconds.

Zone 4: the vehicle decelerates to 50 km / h in 8 seconds and then travels at 50 km / h for a period of 69 seconds (zone 5).

Then, the vehicle accelerates slightly to 70 km / h in 13 seconds (zone 6), by moving at a constant speed of 70 km / h for 50 seconds (zone 7).

In zone 8 vehicle reaches 100 km / h in 35 seconds and then keep the cruising speed for 30 seconds (zone 9).

Further, the vehicle accelerates to 120 km / h for 20 seconds (zone 10), followed by a cruising speed of 120 km / h for 10 seconds (zone 11).

Finally, in zones 12 and 13 vehicle brakes in two steps: in step 1, 16 seconds up to 70 km / h and in step 2 the vehicle is stopped in 18 seconds.

In the last zone (zone 14), the vehicle is stopped for 20 seconds.

The total duration of EUDC driving cycle is 400 seconds and distance covered with an average speed of 62.6 km / h is of 6956 meters.

Figure 5.9. EMS based on PI regulators

4. Results

HPS energy efficiency

Figure 5.10. EMS based on states' diagram

Figure 5.11. EMS based on PI regulators

5. Conclusion

Performance indicator	States' diagram	PI regulators
Battery SoC	70,2%	68,4%
H2 consumption	385 g	155 g
HPS energy efficiency	86,8%	90,9%

Table 5.1. Performance obtained

The EMS based on PI regulators performed better in terms of efficiency, highlighting an overall electrical efficiency with 4% greater in comparison with that obtained with EMS based on states' diagrams, but note that the battery SOC is with 2% lower due to high use (in discharge mode) in the last part of the driving cycle.

The EMS based on PI regulators has achieved but hydrogen consumption noticeably reduced by approx. 40% in comparison with that obtained with EMS based on states' diagrams.

The three criteria adopted for performance comparison of the two control strategies do not allow their hierarchy, because, as has been shown, both strategies shows both advantages and disadvantages during a driving cycle.

4. Possible solutions for advanced EMS

5. Future trends of energy management strategy for FCVs

The latest reviews in field of FCVs' energy management strategy reveals that there are still some issues to be solved and others that must to be improved.

Firstly, the performances of all EMSs are dependent by driving cycle. Therefore, the intelligent-based EMS that will include a driving cycle recognition or driving cycle prediction could be a viable solution to improve the FCV performance. Anyway, these recognition or prediction technologies will increase computation time and the intelligent-based EMSs will be difficult to be implemented as the real-time algorithms. So, the EMS based on load-following technique could be an feasible alternative, being independent by driving cycle.

Secondly, multi-objective EMSs, which integrate into a optimization function the fuel economy, the FC energy efficiency, the safety of FCV, and comfort (drivability), are challenges for high-performance FCVs. Most of proposed EMSs only consider fuel economy of HEV, the FC energy efficiency or both, and few EMSs take into account the last two performance as penalty term in the optimization function.

Thirdly, the compromise between system complexity, level of computation needed and optimization performance of EMSs continue to be an open issue.

Finally, every eEMS has its own advantages and disadvantages. Thus, a standard to make a accurate and convincing evaluation of EMS will be helpful to design a suitable EMS for FCV with specific performance objectives.

1.1. Architecture of the FC RES HPS

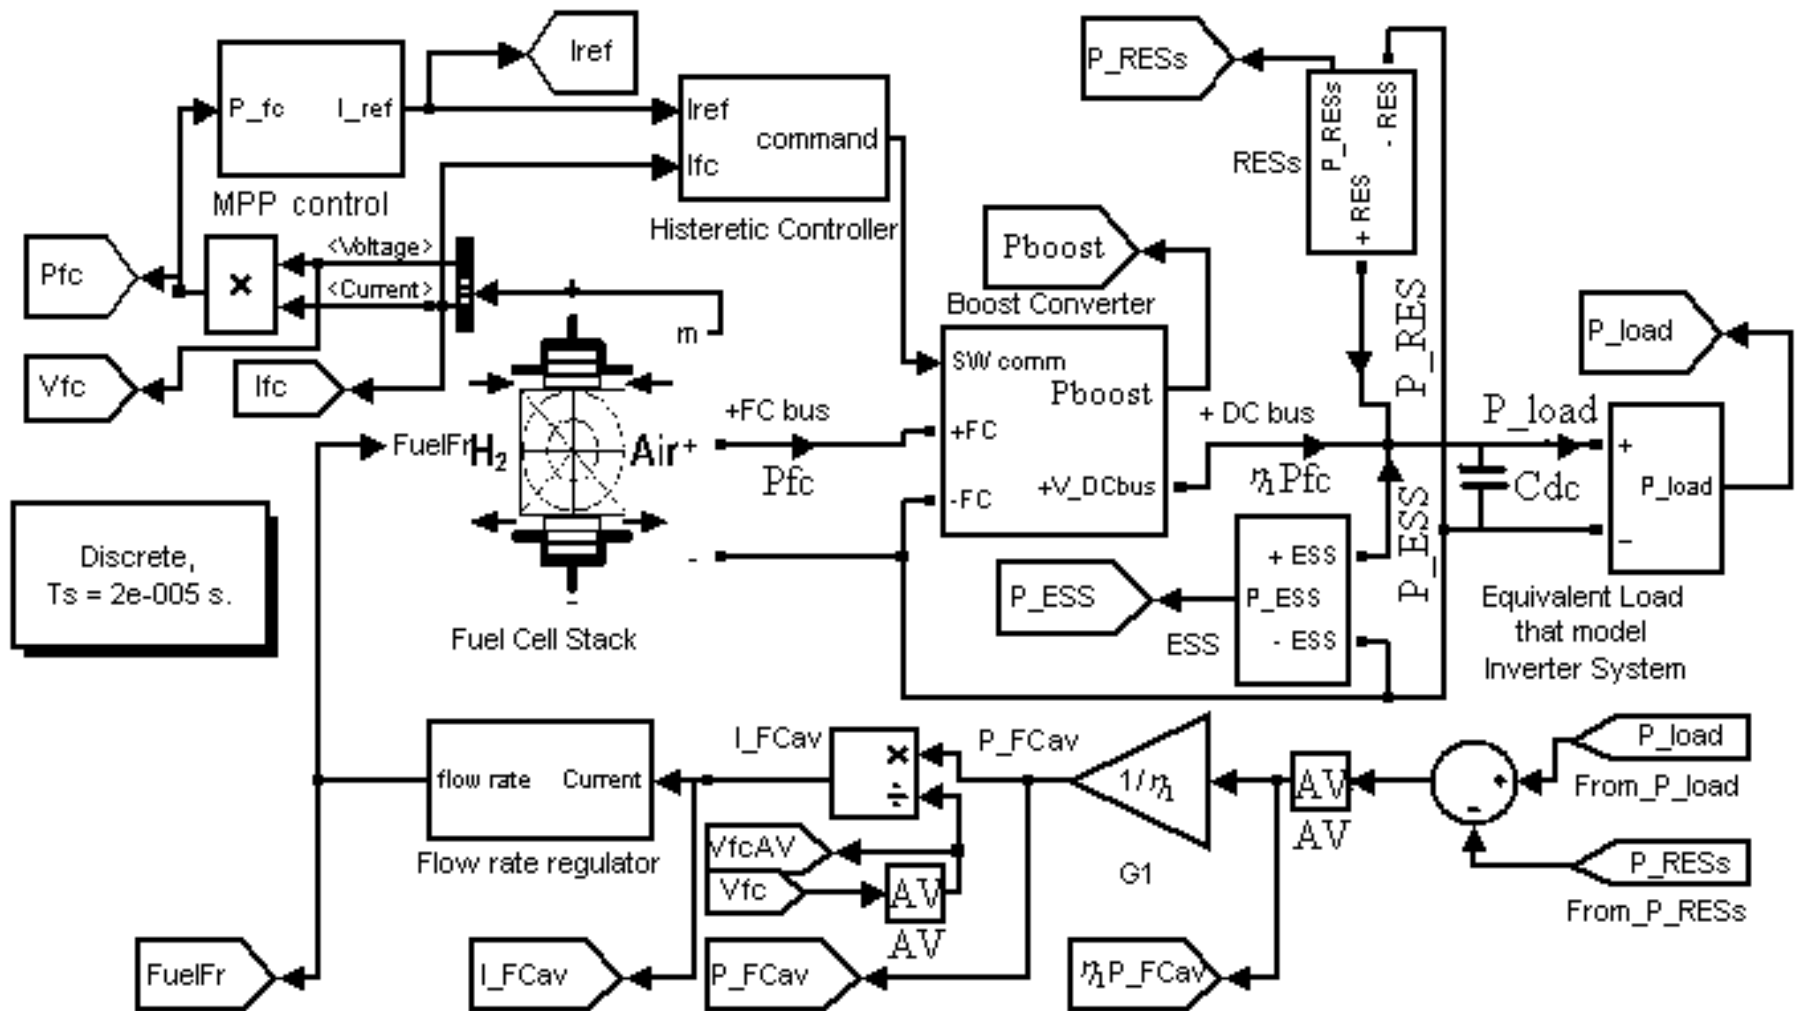

Figure 1. Diagram of FC RES HPS architecture

1. Load-following Mode Control of a FC RES HPS

1.2. Features of the load-following strategy

The load-following strategy has the following features:

- assures the grid active power based on power balancing strategy for the backup power source, which is the FC system;
- optimizes the energy efficiency of the FC system and each RES based on energy harvesting technique of MPP tracking type;
- compensates the energy gap between the load demand and the output power from the RESs and FC based on minimal batteries stack;
- mitigates the impact of HF perturbation on the load power due to the fluctuations of the electric utility grid and RES power based on controlled power flow exchanged with the ultracapacitors stack.

Figure 15. The improvement in the FC net power

2. Improving the PEMFC energy efficiency

2.7. Conclusion

ES control for FuelFr and ES search of the optimum AirFr based on FC current:

- the improvement in the net power $\Delta P_{\text{net}(1\text{fa})}$ increases with a rate of 1.3 W/A ;
- the improvement in the net power $\Delta P_{\text{net}(2\text{fa})}$ increases with a rate of 5.3 W/A
- the relative improvement in the FC net power, $\Delta P_{\text{net}(2\text{fa})} / \Delta P_{\text{net}(1\text{fa})}$, has values in range 1.5 to 1.8.

This means that the PEMFC system must to be mandatory operated close to the MEP if the power losses are high, otherwise the energy efficiency decreases dramatically.

ES control for AirFr and ES search of the optimum FuelFr based on FC current:

- the improvement in the net power $\Delta P_{\text{net}(1\text{af})}$ increases with a rate of 1.6 W/A ;
- the improvement in the net power $\Delta P_{\text{net}(2\text{af})}$ increases with a rate of 1.73 W/A
- the relative improvement in the FC net power, $\Delta P_{\text{net}(2\text{af})} / \Delta P_{\text{net}(1\text{af})}$, has values about of 1.09.

This means that in this case the improvements in FC net power are less sensitive to power losses and load level.

This also sustains that the improvement in the FC net power is less sensitive to power losses if the optimum AirFr is set by the ES controller.

The MEP is more sensitive to FuelFr changes than the changes in AirFr. So, under dynamic load, it is recommended a load following control of the FuelFr and an optimal control of the AirFr based on appropriate strategy that can maximize the energy efficiency.

3. Efficient Energy Control Strategies for FC RES HPS

2.7. Energy Management Unit (EMU) for FC RES HPS

The objectives of this section are:

- (1) To apply the load-following (LF) control based on the MEP tracking (MEPT) control scheme in order to ensure the load demand;
- (2) To improve the fuel consumption and fuel efficiency that are both used as performances indicators based on control of both fuel flow rates;
- (3) To find a methodology to compare the four EMU control topologies based on the performances indicators proposed;
- (4) To shown the advantage of the LF control that operates the ESS in CS mode under any load demand, with direct implications in the size and cost of the RES/FC HPS;
- (5) To shown the advantage of the MEPT control that operates efficiently the FC stack considering the variability of RES and load power profiles, with direct implications in efficiency of the whole RES/FC HPS.

Figure 21. The diagram and power profile of the RES

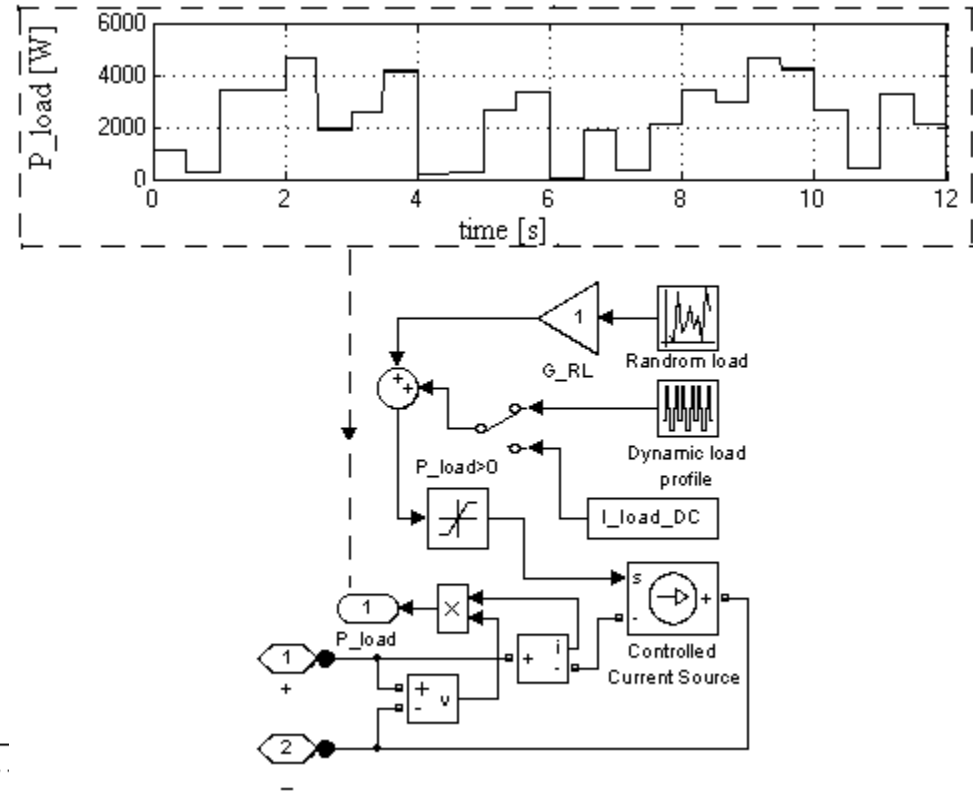

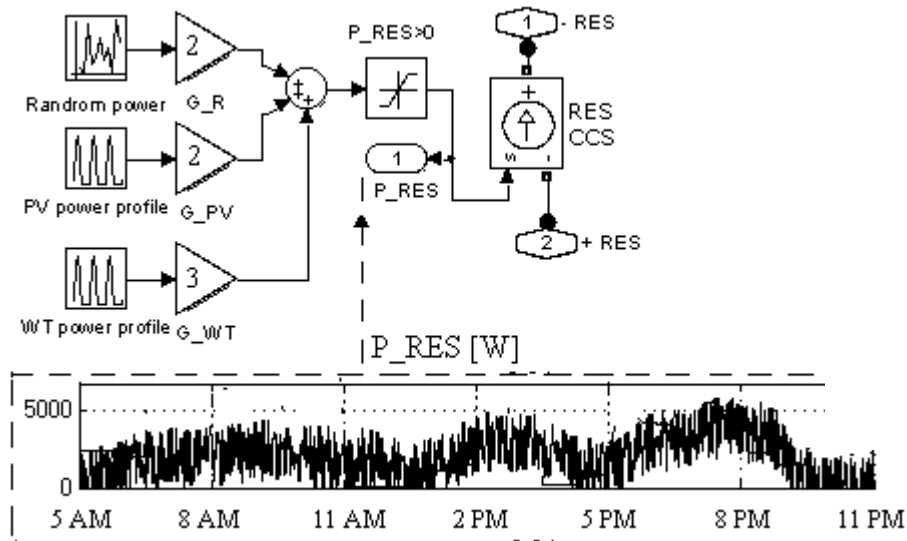

Figure 22. The diagram and power profile of the dynamic load

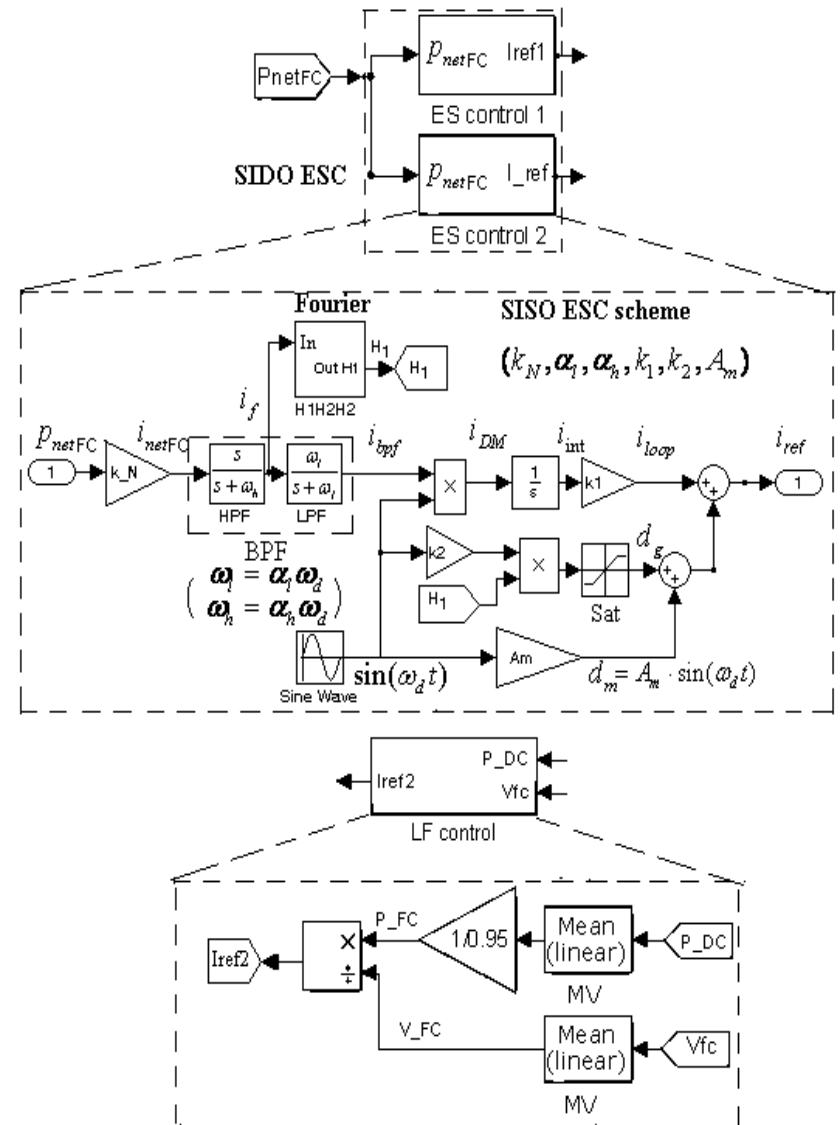

3. Efficient Energy Control Strategies for FC RES HPS

3.4. Energy Management Unit (EMU) for FC RES HPS

All HPS topologies proposed are based on an MEPT and LF control loops that generate the reference currents:

I_{ref} for the boost controller,
and I_{ref1} and I_{ref2} , for the FuelFr and AirFr regulators, respectively.

If I_{FC} current is used to control the FuelFr regulator or the AirFr regulator, instead of the I_{ref1} current, then other two fueling control configurations will be obtained based on the sFF control scheme.

$$P_{RES} + \eta_{boost} P_{FCnet} + P_{ESS} - P_{Load} = 0$$

$$P_{ESS} = 0 \text{ during a drive cycle}$$

$$I_{ref2} = I_{FC(AV)} = (P_{Load} - P_{RES}) / (V_{FC} \eta_{boost})$$

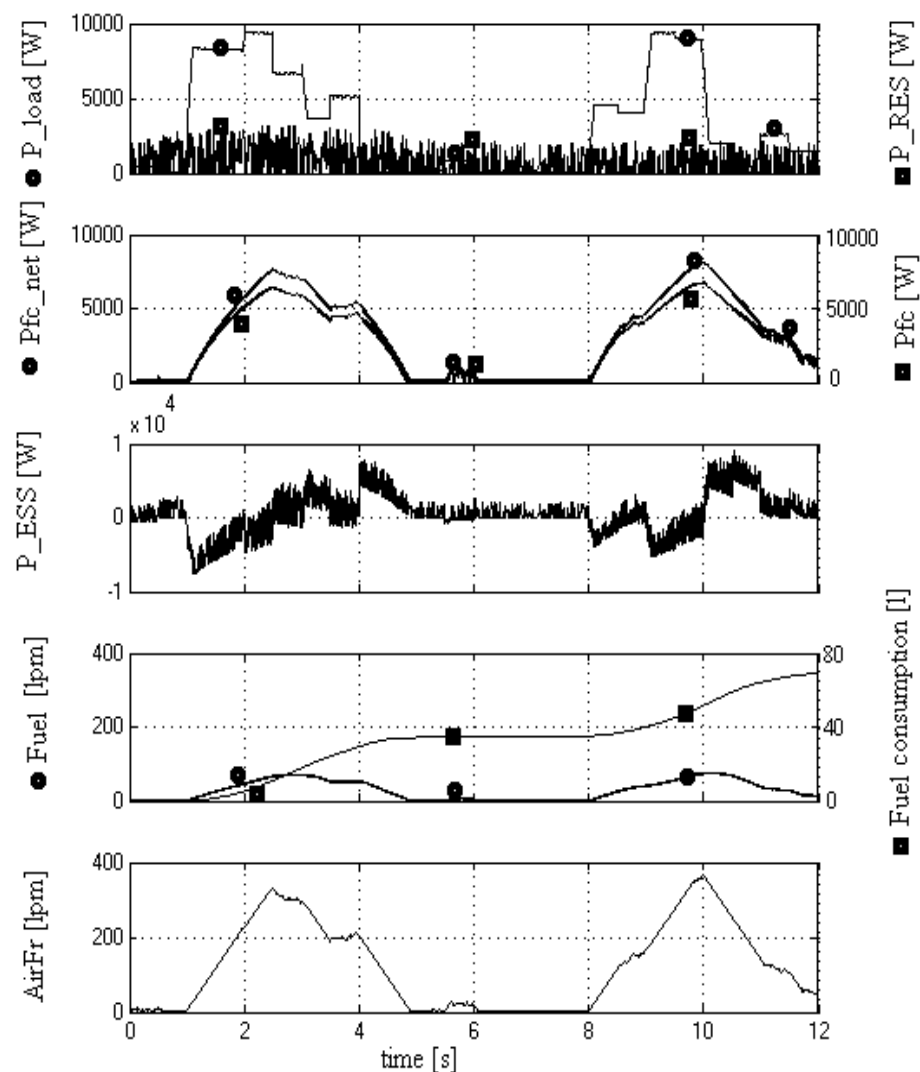

Fig. 32. The FC response for Air-LF/ Fuel-ESC EMU and fuel efficiency under variable load & RES

3. Efficient Energy Control Strategies for FC RES HPS

3.6. Conclusion

The main contributions of the analysis made in this section are the following:

- (1) the Air-sFF/Fuel-LF control topology is more efficient than others control topologies analyzed under different load and RES power profiles (an increase of 3-5% of fuel efficiency indicator was observed in comparison with the Air-LF/Fuel-ESC control topology, which is the next control topology that ensure a high value of the fuel efficiency indicator);
- (2) the fuel consumption is minimum for the Air-ESC/Fuel-LF control topology (the reduction of the fuel consumption value for the Air-ESC/ Fuel-LF control diagram in comparison with the minimum value obtained with other control diagrams depends by the load, being in range of 5-75%);
- (3) both Air-LF/Fuel-ESC and Air-sFF/Fuel-LF control topologies are efficient for the FC HPS under pulsed loads;
- (4) the Air-LF/Fuel-ESC control topology is efficient at FC rated power (an increase of 6.7% of fuel efficiency indicator was observed in comparison with the Air-sFF/Fuel-LF control topology, which is the next control topology that ensure a high value of the fuel efficiency indicator)

Finally, it may be concluded that the performances of the EMU strategy depend by the availability of the RES power, and level and dynamics of the load.

4. Global Maximum Power Point Tracking algorithms

4.1. Global Maximum Power Point (GMPP) algorithms

- The main objective of this section is to present an overview in the Global Maximum Power Point (GMPP) algorithms applied on power generated by the Photovoltaic (PV) arrays.
- Besides this survey on the GMPP algorithms proposed in last decade, the Perturbed-based Extremum Seeking Control (PESC) methods and their applications in PV arrays under Partially Shaded Conditions (PSCs) are investigated as well.
- The PESC schemes proposed to seek and track the GMPP of the PV power will be analyzed as performance obtained for the following indicators:
 - the searching resolution,
 - tracking accuracy,
 - tracking efficiency,
 - tracking speed,
 - and percent of the hit count.

4. Global Maximum Power Point Tracking algorithms

4.1. Performance indicators

The searching resolution (R_s) is defined by:

$$R_s = \frac{\min_i |y_{GMPP} - y_{LMPPi}|}{y_{GMPP}} \cdot 100[\%]$$

The tracking accuracy (T_{acc}) is defined by:

$$T_{acc} = \frac{y_{PV}}{y_{GMPP}} \cdot 100[\%]$$

where y_{PV} is the PV power that is theoretically available and y_{GMPP} is the power extracted by the GMPP algorithm.

The number of iterations to locate the GMPP is a measure of the tracking speed. An iteration for the PESC-based GMPPT algorithms means a dither period (which is a step of scanning). Iteration can be defined for all GMPPT algorithms and it refers to the number of times the specific function of the algorithm is calculated, and this is related only to the method

4. Global Maximum Power Point Tracking algorithms

4.1. Performance indicators

The tracking efficiency (T_{eff}) is given by:

$$T_{eff} = \frac{\int_0^t y_{PV} dt}{\int_0^t y_{GMPP} dt} \cdot 100[\%]$$

The percent of the hit count (PHC) is defined by:

$$PHC = \frac{\text{number of positive results in finding the GMPP}}{\text{number of tests performed}} \cdot 100[\%]$$

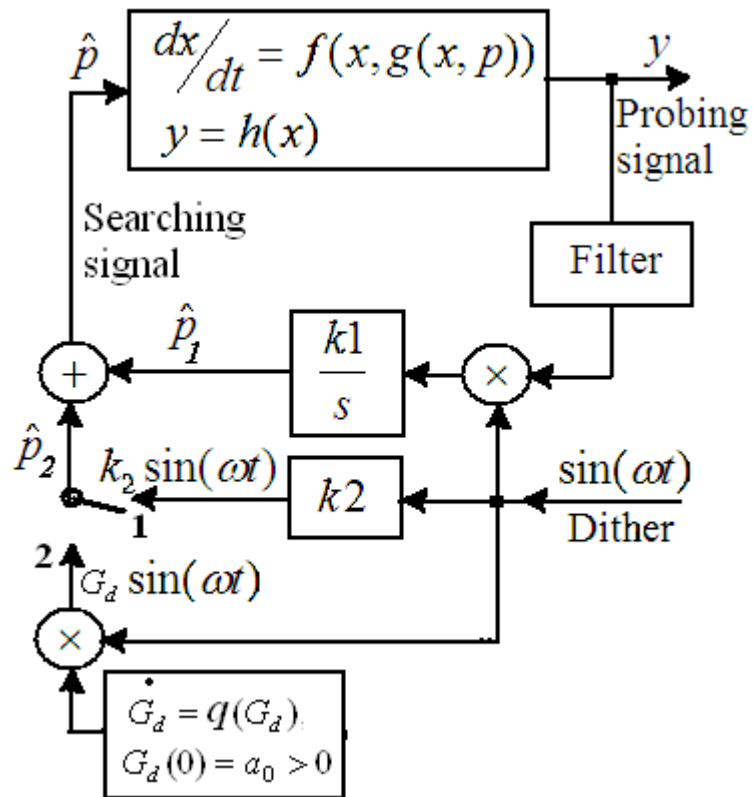

The results obtained will be shown and commented as well. The performance of the PESC-based GMPPT algorithms will be compared with that of other GMPP algorithms proposed in the literature. Different PV and nonlinear multimodal patterns will be used to test the PESC-based GMPPT schemes. The results obtained under different PSCs simulated have shown a very good performance related to search speed and tracking accuracy of the PESC-based GMPPT algorithms.

4. Global Maximum Power Point Tracking algorithms

4.2. Asymptotic Perturbed Extremum Seeking Control (aPESC) scheme

- The first Asymptotic Perturbed Extremum Seeking Control (aPESC) scheme was proposed in [41] for GMPP search based on Scalar PESC (PESCs) scheme. The PESCs scheme and its Asymptotic variant (aPESCs) are shown in Figure 1 for switch in position (1) and (2).

- [41] Tan Y, Nešić D, Mareels I, Astolfi A. On global extremum seeking in the presence of local extrema. Automatica

• Figure 1. The scalar PESC (PESCs) scheme and its asymptotic variant (aPESCs)

• Figure 2. The aPESC schemes based on (1) the Lyapunov function (aPESCLy) and (2) the H1 harmonic (aPESCH1)

4. Global Maximum Power Point Tracking algorithms

4.2. Asymptotic Perturbed Extremum Seeking Control (aPESC) scheme

• The tracking loop is the same for all aPESC schemes proposed in the literature and contains the following signal processing blocks of the process output ($y=y_{CC}+y_{AC}$): the filtering (of the CC value, y_{CC}), demodulation (product of the AC value, y_{AC} , with the dither signal), integration (of the demodulated signal), and amplification (with k_1). The filter can be of High-Pass Filter (HPF) type or Band-Pass Filter (BPF) type. The average value of the gradient for the tracking signal is given by:

$$\frac{d\bar{p}_1}{dt} = \frac{A^2 \cdot k_1}{2} \cdot \frac{dy}{dx} \xrightarrow{A=1} \frac{d\bar{p}_1}{dt} = \frac{k_1}{2} \cdot \frac{dy}{dx}$$

• The sweeping signal (p_2) can have different expressions depending on the asymptotic function chosen to modulate the dither:

- The asymptotic function is based on an exponential implementation [41];
- The asymptotic function is obtained through commutation between constant and exponential amplitude of dither based on the Lyapunov switching function [44];
- The asymptotic function is based on the magnitude of first harmonic (H1) of the process output, which is obtained with Fast Fourier Transform (FFT)

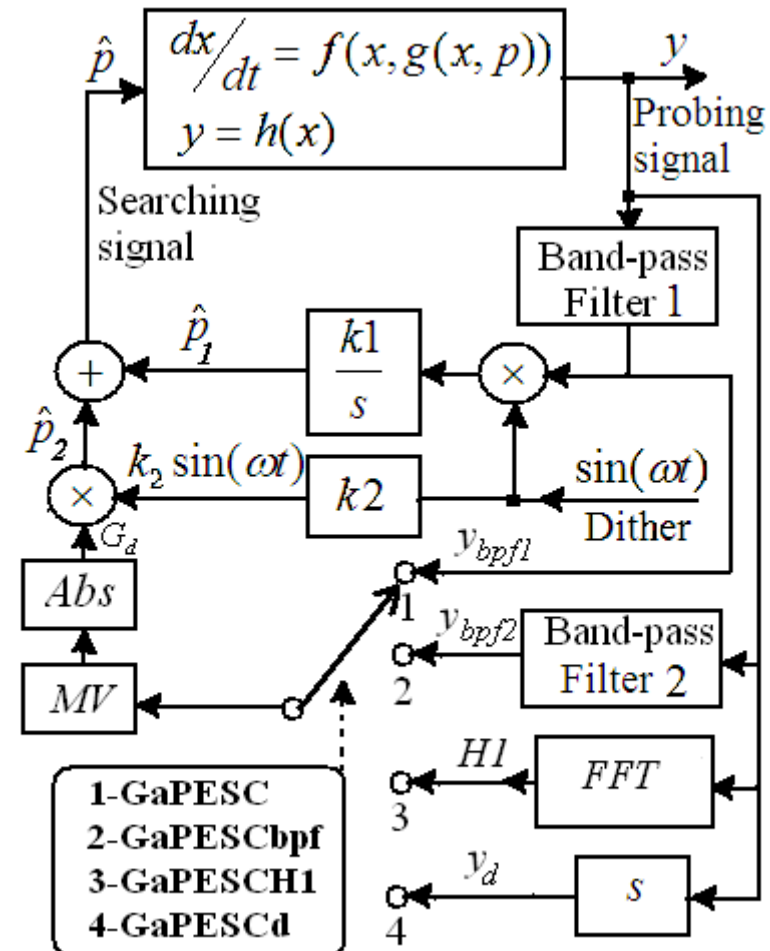

4. Global Maximum Power Point Tracking algorithms

4.3. Proposed Global aPESC schemes

The H1 magnitude of the process output can be approximated by using a BPF2 centered on the first harmonic, a derivative operator, or the BPF1 (see Figure 3). Thus the following variants of the aPESCH1 scheme can be obtained in order to be tested for GMPP search:

- (1) the GaPESC scheme based on the BPF1,
- (2) the GaPESCbpf scheme based on the BPF2,
- (3) the GaPESCH1 scheme based on the H1 magnitude computed with the FFT, and
- (4) the GaPESCd scheme based on the derivative operator.

- If the BPF2 is designed to approximate the H1 magnitude, then the behavior of both GaPESCBpf and GaPESCH1 schemes are almost the same. So, only GaPESCH1 scheme will be considered below.

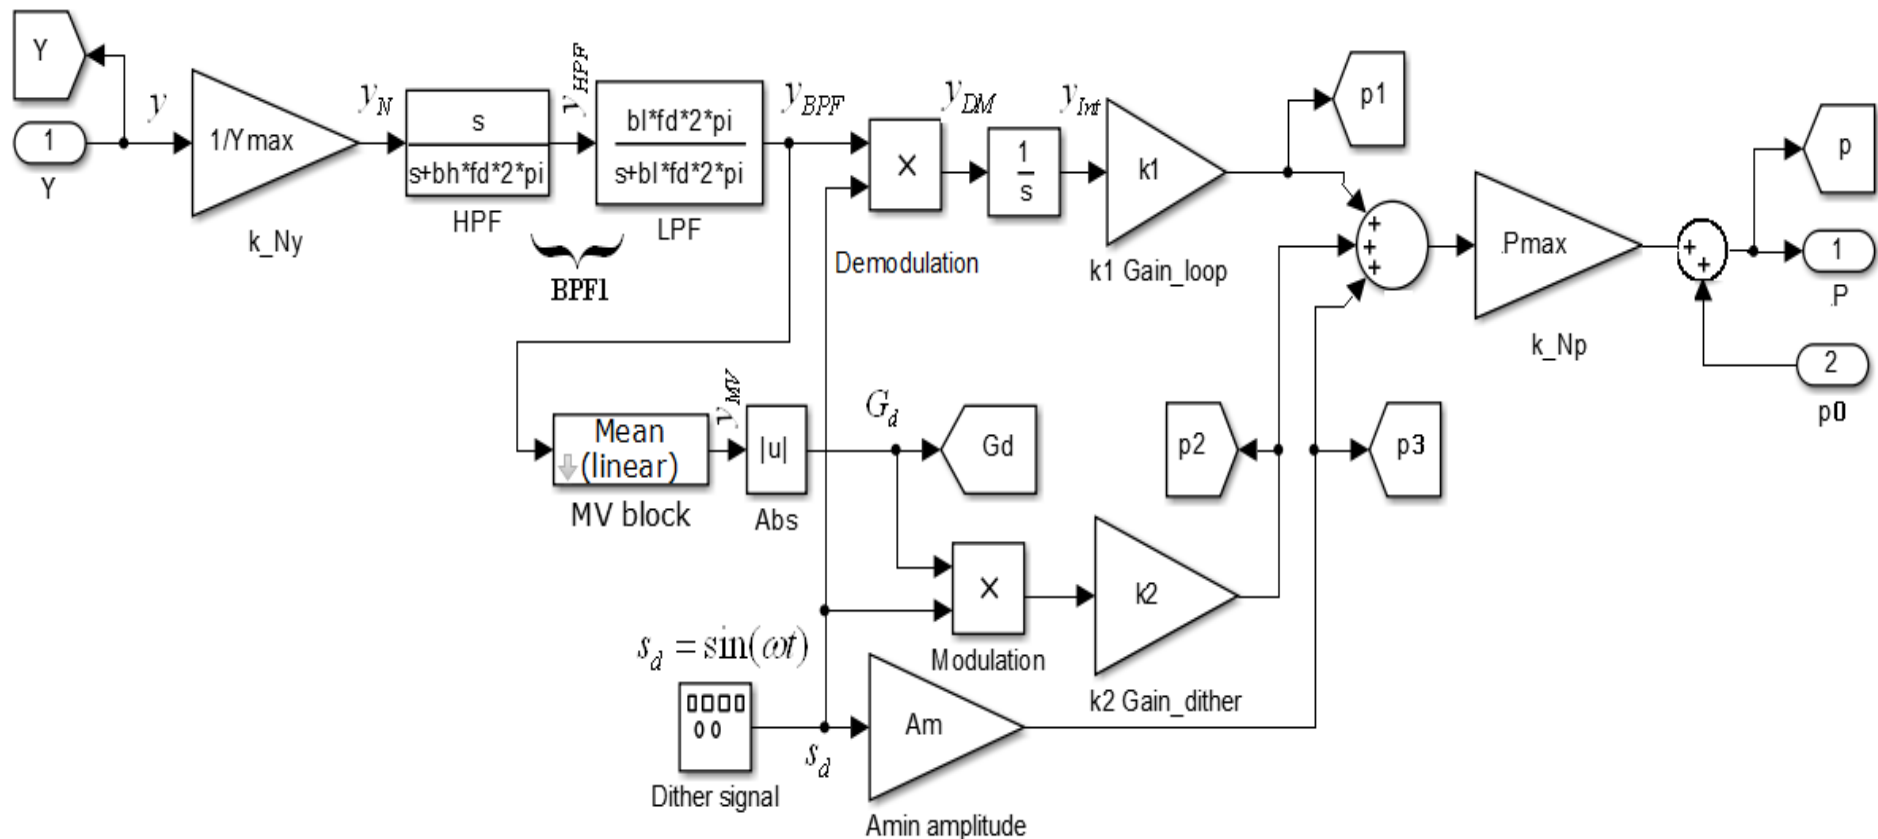

- **Figure 3. The aPESC schemes**

4. Global Maximum Power Point Tracking algorithms

4.4. GaPESC scheme

Figure 4. The diagram of the GaPESC scheme

4. Global Maximum Power Point Tracking algorithms

4.4. GaPESC scheme parameters

The parameters used in simulation are the following:

- the dither frequency is $f_d = 1/T_d = \omega/2\pi = 100$ Hz;
- the dither amplitude is set to 1;
- the cut-off frequency of the HPF1, $f_{h1} = \beta_{h1} \cdot f_d$, where $\beta_{h1} = 0.1$;
- the cut-off frequency of the LPF1, $f_{l1} = \beta_{l1} \cdot f_d$, where $\beta_{l1} = 1.9$ in order to approximate the H1 amplitude [40];
- the cut-off frequency of the HPF2, $f_{h2} = \beta_{h2} \cdot f_d$, where $\beta_{h2} = 0.5$;
- the cut-off frequency of the LPF2, $f_{l2} = \beta_{l2} \cdot f_d$, where $\beta_{l2} = 5.5$ in order to increase the dither persistence on the control loop [46];
- the minimum amplitude of dither, A_m , is set to 0.001, but can be smaller than this value in order to obtain a very low ripple on the probing signal during the stationary phases;
- the normalization gains, $k_{Ny} \cong 1/y_N$ and $k_{Np} \cong p_N$, where the p_N value sets the initial amplitude of the dither and the y_N value is chosen in the range of maximum and minimum values estimated for the GMPP on the nonlinear map, $y = h(p)$; $k_{Ny} = k_{Np} = 1$ for the nonlinear map (6); note that ' \cong ' means in a large range around the mentioned value;
- the gain of the dither amplitude, $k_2 \cong \Delta p$, where $\Delta p = |p_{GMPP} - p_0|$, and p_0 is the initial value for starting the search of the p_{GMPP} ; $k_2 = 3$ for the nonlinear map (6);
- the loop gain, $k_1 = \gamma_{sd} \cdot \omega$, where $\gamma_{sd} = 1.5$ was set based on the dynamic performance analysis shown below.

4. Global Maximum Power Point Tracking algorithms

4.10. GMPP search under noisy PSC based on the GaPESC scheme

4. Global Maximum Power Point Tracking algorithms

4.11. Conclusions

- The maximum, minimum and average value of the tracking accuracy reported for GaPESC scheme is of 99.99%, 99.95% and 99.97%
- The tracking efficiency of 99.97%
- The resolution of all schemes is lower than 0.25% ($\cong 1/402$).
- The robustness of the GMPP searching was tested for two PV patterns' sequences
- Each time the GMPP of the PV pattern from the noiselessly sequence was accurately tracked.
- The level of GMPP of the PV pattern from the noisy sequence is changed randomly at each 10 milliseconds. Therefore, the GaPESC scheme searches continuously the current GMPP.
- Based on the performance shown and its simplicity of implementation, the GaPESC scheme is competitive with similar techniques to scan the GMPP or other advanced GMPP algorithms proposed.
- Furthermore, the tuning ranges for the design parameters are relatively large because the GaPESC scheme is based on adaptive control of ESC type.

Summarizing, the research directions in field of the RES/FC HPS that are approached in the studies mentioned above are the following:

- The RES need advanced control techniques to harvest all power available, operating the RES close to MPP. This control is mandatory due to poor efficiency of solar PV, which is the main impediment in encouraging its use until the PV technology will be improved.
- The power losses in power interfaces have been substantially reduced using advanced topologies, switches and appropriate control scheme, eventually integrated in multiport power converter structure. In general, the energy efficiency of power converters used in HPS is higher than 95%.
- The hybrid batteries/ultracapacitors ESS is used in HPS to ensure the power flow balance on the DC bus, but their life-cycle need to be improved through innovative technologies, too. The CS mode proposed here for the ESS can improve the life-cycle of the batteries stack, besides other advantages such as reduced size and low costs of the ESS.
- The cost reduction could be an incentive for the producers of HPS to implement such systems that will ensure decreasing of the payback time for the capital invested.

Summarizing,

- The hydrogen technology (to generate and store hydrogen) is still a costly and unsafe technology. So, alternative technologies based on fuel reformers are developed at low cost. Furthermore, the PEMFC system must be operated at the MEP to increase the energy efficiency of the entire RES/FC HPS, as it is proposed here.
- These standalone RES/FC HPSs based on EMU strategies must to predict the RES power available or be adaptable to RES power fluctuations to sustain any unpredictable load demand. The LF control proposed here could be a solution, because it is very simple to be implemented in the commercial RES/FC HPS, requesting only software upgrade and few circuits reconfiguration.
- The protection issue, especially for use of PEMFC system and batteries stack from the ESS, are identified and implemented in EMU of the commercial RES/FC HPS. The proposed protection measures are also implemented in simulation diagram shown here, but this issue was not extensively studied, being outside of the scope of this presentation.

$$P_m = c_p(\lambda, \beta) \frac{\rho A}{2} v_{wind}^3 \quad c_p(\lambda, \beta) = c_1 \cdot \left(\frac{c_2}{\lambda_i} - c_3 \beta - c_4 \right) \cdot \exp\left(-\frac{c_5}{\lambda_i}\right) + c_6 \lambda \quad \frac{1}{\lambda_i} = \frac{1}{\lambda + 0.08\beta} - \frac{0.035}{\beta^3 + 1}$$

$$T_m = \frac{P_m}{\omega_m} \quad P_{m(pu)} = k_p \cdot c_{p(pu)}(\lambda, \beta) \cdot v_{wind(pu)}^3 \quad \lambda = \frac{R\omega_m}{v_w}$$

where c_p is WT performance coefficient, ρ is air density (kg/m^3), $A = \pi R^2$ is WT swept area (m^2), R is radius of the turbine blade, λ is tip - speed ratio (TST), β is the blade pitch angle (degree), and k_p is the power gain ($k_p = 0.73$, $c_1 = 0.5176$, $c_2 = 116$, $c_3 = 0.4$, $c_4 = 5$, $c_5 = 21$, and $c_6 = 0.0068$ for WT model used ($P_m = 1500$ W, the base power of the electrical generator is 1.5/0.9 MVA, and base wind speed is 12 m/s) and the pu values are obtained through normalization of current values to base values)

Real-time Optimization of FC / Renewable HPS

The Real-Time Optimization (RTO) strategies are proposed to efficiently operate different nonlinear energy systems such as the mixed heating systems and photovoltaic arrays.

The RTO strategies were recently proposed to increase the fuel economy of the Fuel Cell Hybrid Power Sources (FCHPS), which can also improve their cost, durability and reliability. The RTO strategies must assure the operation of FCHPS at maximum power efficiency based on efficient control of power flows from renewable energy sources.

As it is known, the RTO strategies can be based on optimization's rules (the rule-based strategies) or optimization's functions.

For example, the tracking efficiencies of 99.60%, 99.41%, and 99.28%, and the tracking times of 12 ms, 33 s, and 25 s are reported for systems of photovoltaic (PV) panels, fuel cell (FC) stacks, and wind turbines (WT).

The deterministic rule-based strategies are of sub-optimal type and cannot guarantee that the optimal solution (the GMP) will be always found. But these strategies are the easiest to be implemented, so these are already available in the market.

On the other hand, even if the optimization-based strategies are difficult to be implemented, the recent RTO applications for FC vehicle (FCV) request advanced RTO strategies because the GMP must be found in any operating condition requested.

Real-time Optimization of FC / Renewable HPS

RTO strategies are based on:

- I. the Equivalent Consumption Minimization Strategy (ECMS)
- II. the intelligent algorithms
- III. the Model Predictive Control (MPC)
- IV. the hybrid techniques using
 - the wavelet-fuzzy logic control
 - the robust-adaptive sliding mode control
 - the combinatorial optimisation approach
 - the multi-scheme method
 - double layer metaheuristic technique
 - and so on

The ECMS is most known RTO strategy used for FCHPS considering

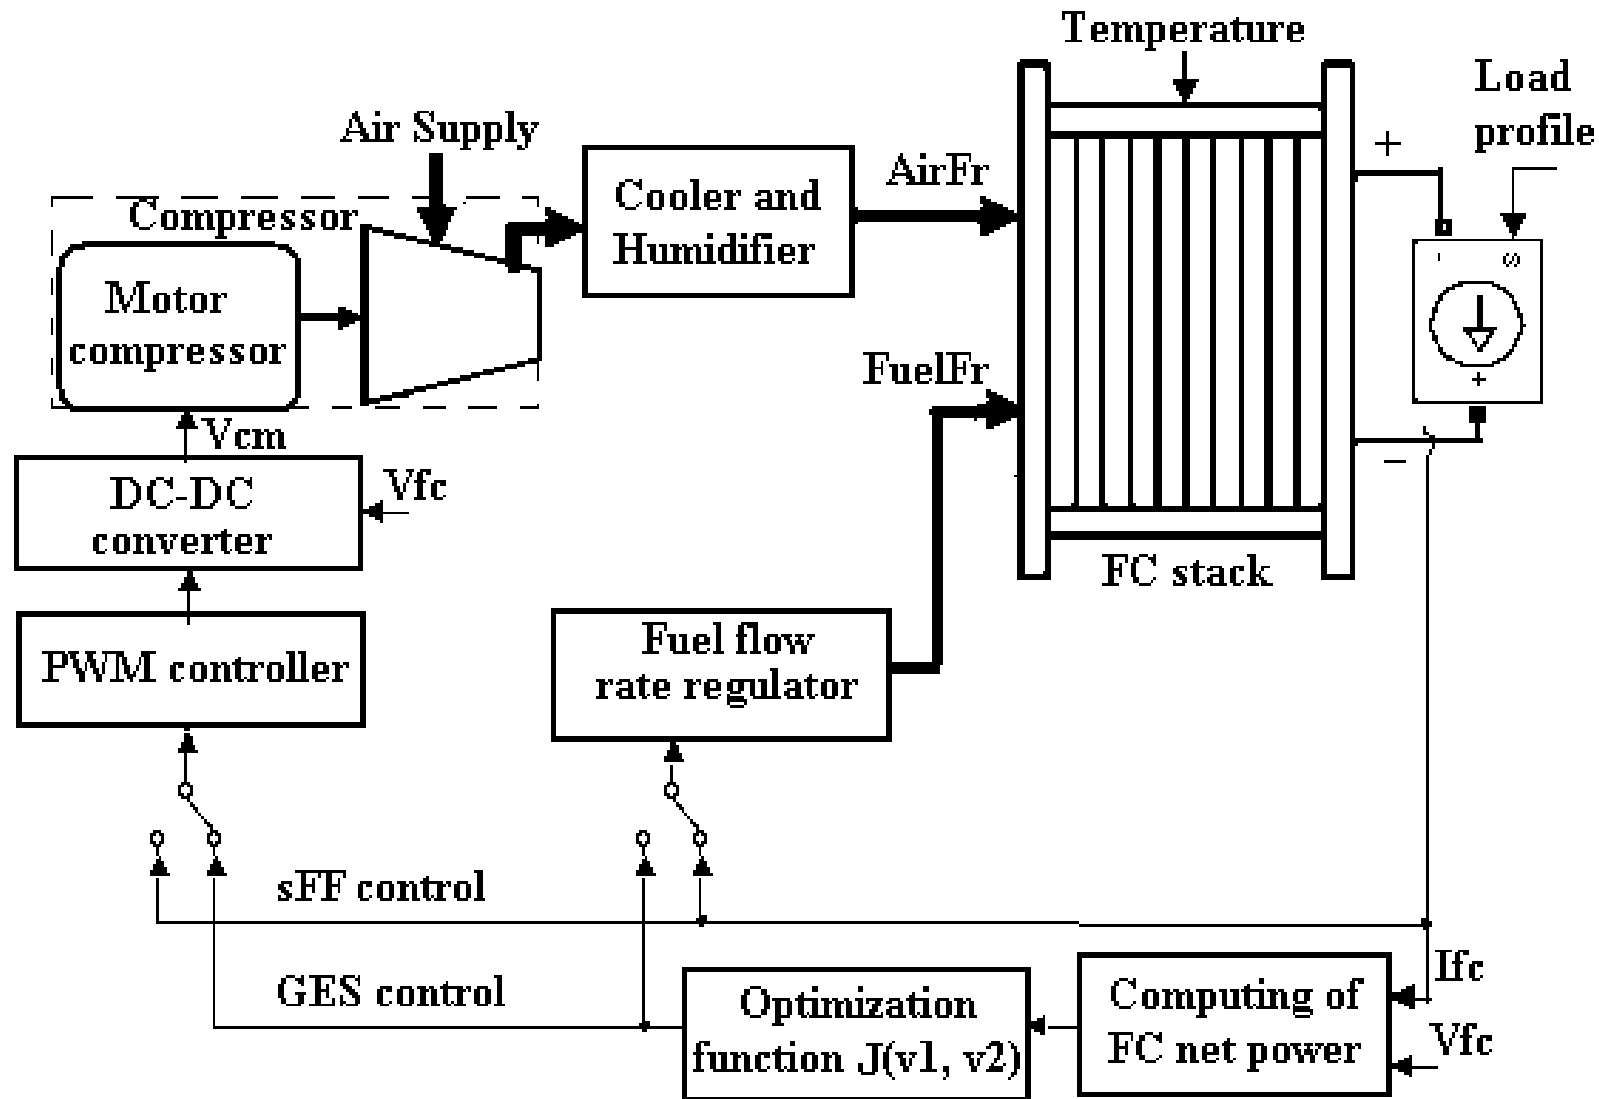

- the Pontryagin's Minimum Principle (PMP) or
- Dynamic Programming (DP).

The RTO strategies based on the Extremum Seeking (ES) algorithms have been proposed recently for FCHPS and FC vehicles.

The optimization function (J) is defined as mix of FC net power (P_{FCnet}) and Fuel Consumption Efficiency ($Fuel_{eff}$) using the weighting coefficients k_{net} and k_{fuel} :

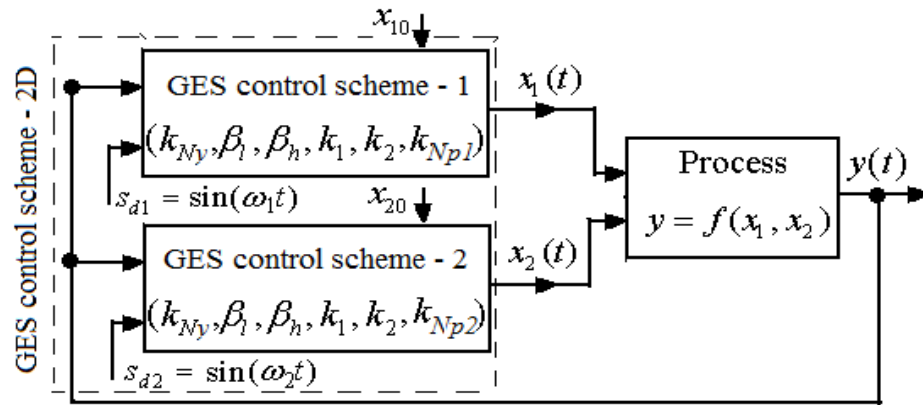

$$J(x_1, x_2) = k_{net} P_{FCnet} + k_{fuel} Fuel_{eff}$$

Real-time Optimization of FC / Renewable HPS

The simulation diagram

The Himmelblau's function

$$f_H(x_1, x_2) = (x_1^2 + x_2 - 11)^2 + (x_1 + x_2^2 - 7)^2$$

$$f(x_1, x_2) = GMP - f_H(x_1, x_2)$$

The function $f(x_1, x_2)$ has four GMPs located at M_i , $i=1,2,3,4$, in the searching area (top); searching of each GMP starting from initial point close to it (bottom)

Real-time Optimization of FC / Renewable HPS

The Himmelblau's function has one local maximum point (LMP),
 $f(-0.270845, -0.923039) = 181.617$, and
four identical local minimum points (LmP):
 $f(-2.805118, 3.283186) = 0.0$,
 $f(3.0, 2.0) = 0.0$,
 $f(-3.779310, -3.283186) = 0.0$, and
 $f(3.554428, -1.848126) = 0.0$.

So, function $f(x_1, x_2)$ has four identical
GMPs at

$(x_{1(M1)}, x_{2(M1)}) = (-2.805118, 3.283186)$,
 $(x_{1(M2)}, x_{2(M2)}) = (3.0, 2.0)$,
 $(x_{1(M3)}, x_{2(M3)}) = (-3.779310, -3.283186)$,
and $(x_{1(M4)}, x_{2(M4)}) = (3.554428, -1.848126)$,
and one LmP, $f(-0.270845, -0.923039) =$
GMP - 181.617, where GMP = 200).

The multimodal benchmark patterns must
have only one GMP, so four multimodal
functions were defined :

$$f_{Mi}(x_1, x_2) = f(x_1, x_2) - r \cdot \left[(x_1 - x_{1(Mi)})^2 + (x_2 - x_{2(Mi)})^2 \right], i = 1, 2, 3, 4$$

The searching of the GMP_{M1} in the phase plane (top) and on the $f_{M1}(x_1, x_2)$ (bottom) if the starting point is (0,0).

Real-time Optimization of FC / Renewable HPS

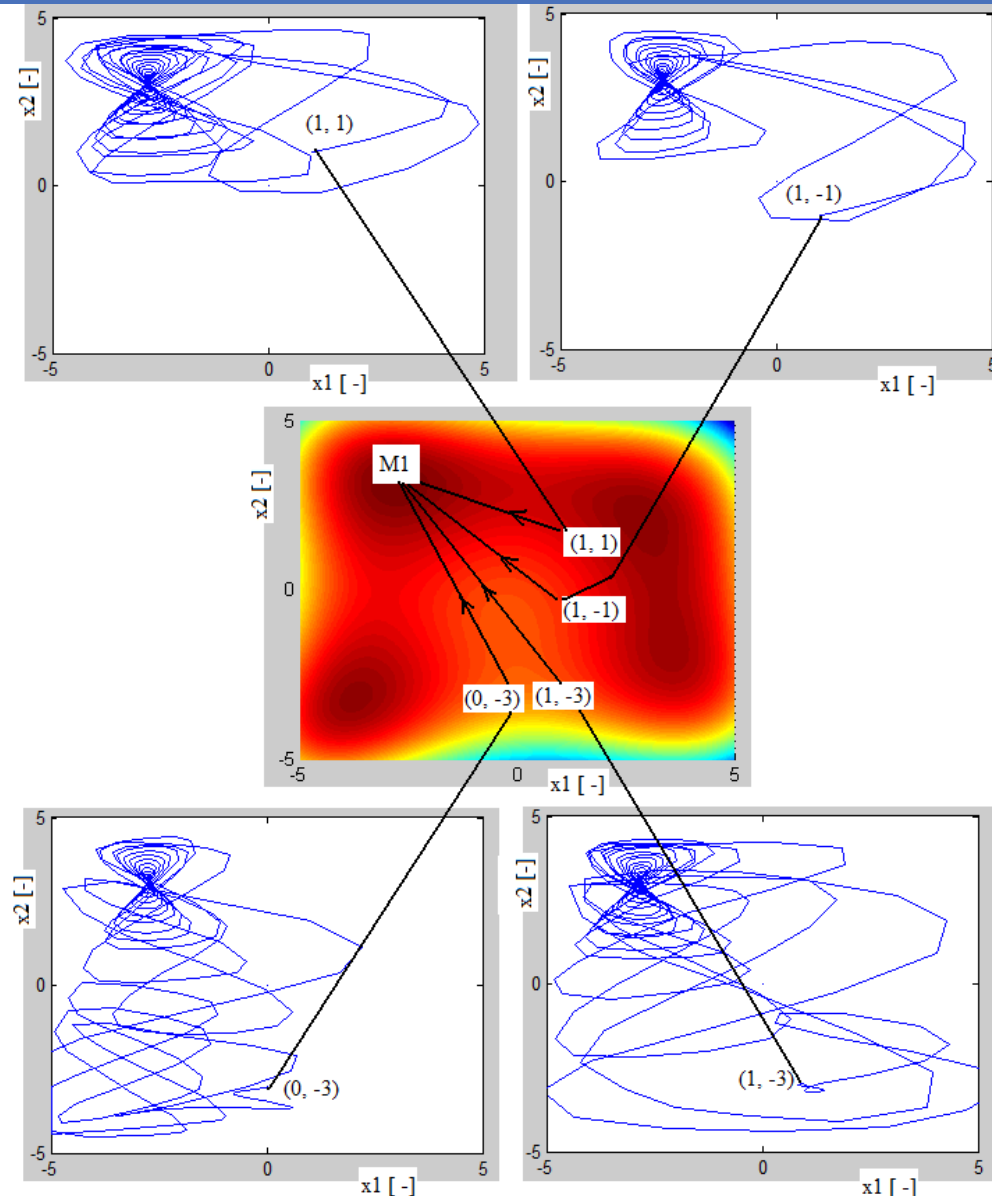

The parameter r sets the searching resolution (R_s)

$$R_s = \frac{\min_i |GMP - LMP_i|}{GMP} \cdot 100[\%]$$

Each function f_{Mi} has one GMP and three LMPs in the searching space. The searching resolution is of 8.75%, 3.65%, 10.06%, and 3.79% for f_{Mi} pattern, $i=1-4$.

Parameters of the GES control scheme ($i=1,2$):

- the dithers' frequencies:
 $\omega_1 = \omega = 50$ Hz, $\omega_2 = 2\omega = 100$ Hz;
- the ESC loops' gains (tuning parameters):
 $k_{1(i)} = 4\omega_i$;
- the dithers' gains (tuning parameters):
 $k_{2(i)} = 2$;
- the normalization gains:
 $k_{Np(i)} = 10$, $k_{Ny(i)} = 200$;
- the BPF cut-off frequencies:
 $\omega_{l(i)} = 3.5\omega_i$, $\omega_{h(i)} = 0.1\omega_i$;
- the minimum amplitude of the dither $p_{3(i)}$:
 $A_m = 0.001$.

The searching of the GMP_{M1} in the phase plane, starting from different points

Real-time Optimization of FC / Renewable HPS

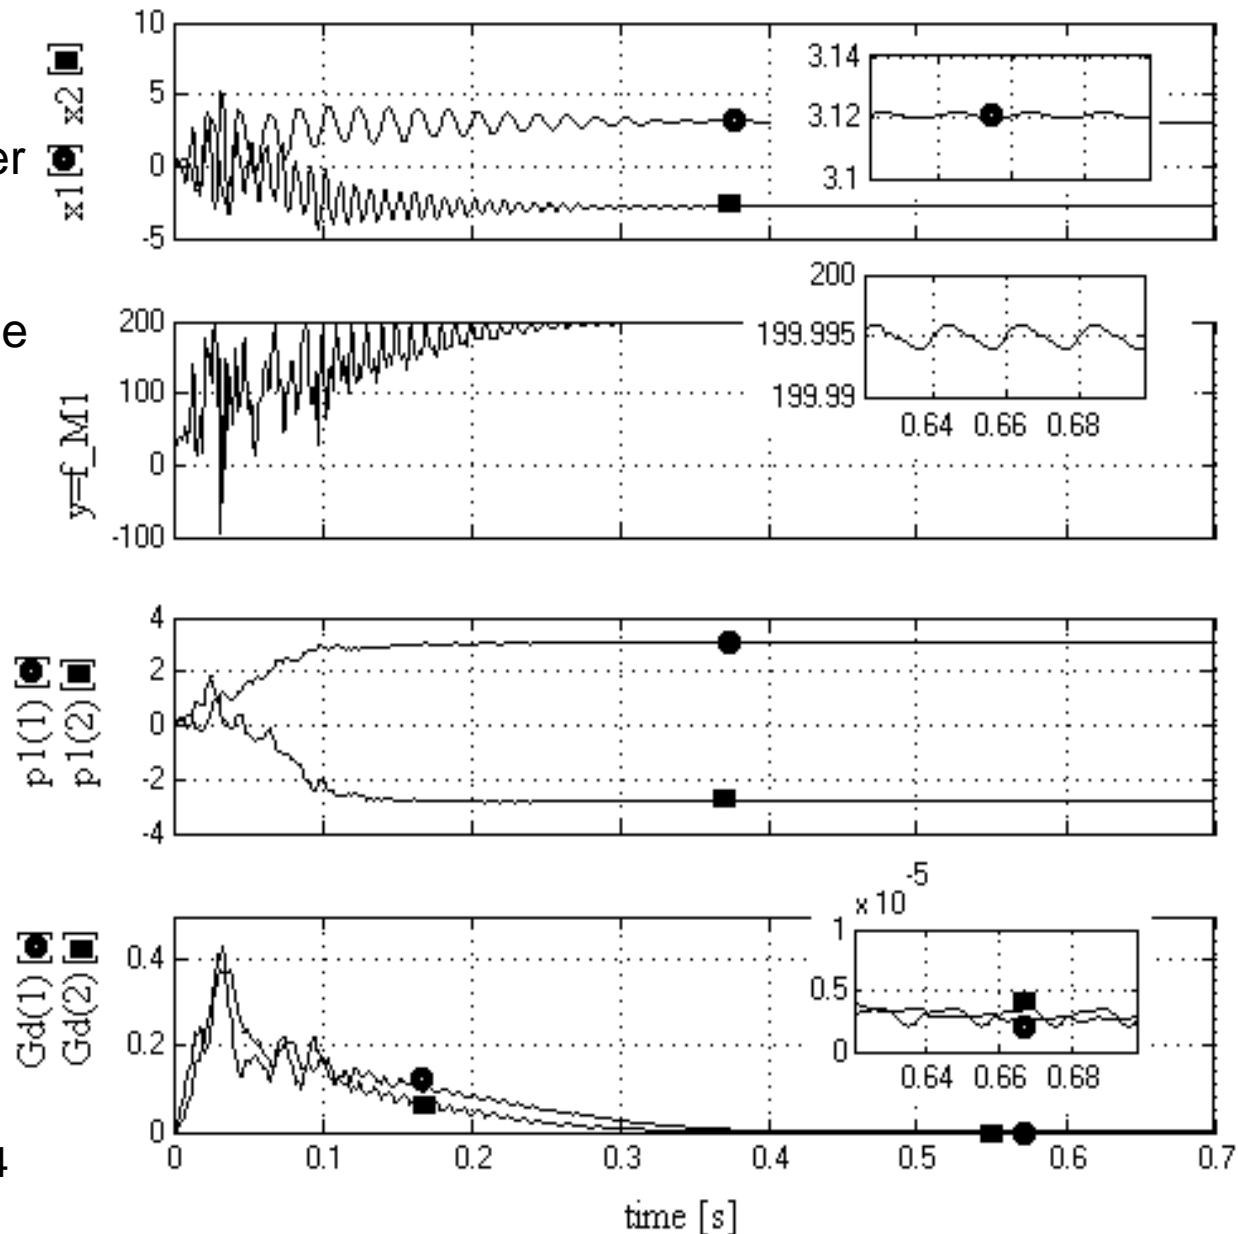

The tracking speed:
is less than 0.4 seconds;
The tracking accuracy is higher
than 99.99%;
The oscillations during the
stationary regime are negligible

The tracking accuracy (T_{acc})
is defined by :

$$T_{acc} = \frac{y_{GMP}^*}{y_{GMP}} \cdot 100[\%]$$

where y_{GMP} is the global
extreme, $y_{LMP} < y_{GMPP}$ is a
local maxima and $y_{GMPP}^* < y_{GMPP}$
is the value tracked
with the GMPT algorithm.
